This program uses simplex tableau. First, the initial matrix is created using the input arrays. Then, the `simplex_pivot_column` function selects the largest coefficient and `simplex_pivot_row` uses the selected column to select by the pivot row based on the smallest ratio. Then, the Gauss-Jordan elimination is performed to make the rest of the pivot column entries 0.

This effectively solves the linear programming problem by reaching the optimal solution through repeatedly improving the objective function through simplex iterations until the optimal solution is achieved. For this lab, the built-in driver was used for correctness.
